## Appendix IV:C. Methods for Estimating HPD Attenuation

### Appendix IV:C. Methods for Estimating HPD Attenuation

The actual effectiveness of any individual hearing protector cannot be determined under workplace conditions.

However, OSHA's noise standards ([29 CFR 1910.95\(j\)\(2\)](#) and [29 CFR 1926.52\(d\)](#)) require that personal hearing protection be worn to attenuate the occupational noise exposure of employees to within the limits shown in Tables [G-16](#), [G-16a](#), and [D-2](#), respectively. Hearing protectors are evaluated under laboratory conditions specified by the American National Standards Institute in ANSI S3.19-1974 (OSHA's experience and the published scientific literature indicate that laboratory-obtained real ear attenuation for hearing protectors can seldom be achieved in the workplace).

- [Appendix B: Methods For Estimating the Adequacy of Hearing Protector Attenuation](#) provides information on how to determine the adequacy of hearing protector attenuation using the noise reduction rating (NRR) of a given hearing protector.
- Use the following formulas to estimate the attenuation afforded to a noise-exposed employee in a work environment by muffs, plugs, or a combination of both.

- A common method used for **single protection** (either muffs or plugs) is as follows

1. Determine the laboratory-based noise attenuation provided by the HPD. This is referred to as the Noise Reduction Rating (NRR) and is listed on the packaging.
2. Subtract the NRR from the C-weighted TWA workplace noise level, as follows:

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBC)} - \text{NRR}$$

If C-weighted noise level data is not available, A-weighted data can be used by subtracting a 7 dB correction factor from the NRR, as follows:

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBA)} - (\text{NRR} - 7)$$

*Example:*

TWA=100 dBA, muff NRR=19 dB

$$\text{Estimated Exposure} = 100 - (19-7) = 88 \text{ dBA}$$

- For **dual protection** (ear muffs and plugs are used simultaneously) use the following:

1. Determine the laboratory-based NRR for the **higher** rated protector ( $\text{NRR}_h$ ).
2. Subtract 7 dB from  $\text{NRR}_h$  if using A-weighted sound level data.
3. Add 5 dB to the field-adjusted NRR to account for the use of the second hearing protector.
4. Subtract the remainder from the TWA as follows:

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBC)} - (\text{NRR}_h + 5), \text{ or}$$

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBA)} - [(\text{NRR}_h - 7) + 5]$$

*Example:*

TWA=110 dBA, plug NRR=29, and muff NRR=25 dB

$$\text{Estimated Exposure} = 110 - [(29 - 7) + 5] = 83 \text{ dBA}$$

- OSHA's experience and the published scientific literature have shown that laboratory-obtained real ear attenuation for HPDs can seldom be achieved in the workplace. To adjust for workplace conditions, **OSHA strongly recommends applying a 50% correction factor** when estimating field attenuation. This is especially important when considering whether engineering controls are to be implemented. The equations above would then be modified as follows:

- Single Protection:

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBC)} - [\text{NRR} \times 50\%], \text{ or}$$

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBA)} - [(\text{NRR} - 7) \times 50\%]$$

- Dual Protection:

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBC)} - [(\text{NRR}_h \times 50\%) + 5], \text{ or}$$

$$\text{Estimated Exposure (dBA)} = \text{TWA (dBA)} - \{[(\text{NRR}_h - 7) \times 50\%] + 5\}$$
